HANDWRITTEN DIGIT RECOGNITION

Project Report

---

1. PROJECT OVERVIEW

1.1 Objective

The primary objective of this project is to develop and compare multiple machine learning models for recognizing handwritten digits from the MNIST dataset. The project implements three different algorithms from both scikit-learn and from scratch, evaluates their performance, and explores optimization techniques like ensemble learning and dimensionality reduction.

1.2 Dataset

- Name: MNIST (Modified National Institute of Standards and Technology)
- Total Images: 70,000 handwritten digits
- Image Size: 28 × 28 pixels
- Features: 784 pixels per image (0-255 grayscale values)
- Classes: 10 digits (0 through 9)
- Training Set: 56,000 images (80%)
- Testing Set: 14,000 images (20%)

1.3 Technologies Used

Technology	Purpose
Python 3.x	Core programming language
scikit-learn	ML algorithms, preprocessing, PCA

NumPy	Numerical computations
Pandas	Data manipulation
Matplotlib & Seaborn	Data visualization
Graphviz	Flow diagram generation
Google Colab	Development environment

2. METHODOLOGY

2.1 Project Flow Diagram

HANDWRITTEN DIGIT RECOGNITION - PROJECT WORKFLOW

```
📁 START
  ↓
🔍 STEP 1: DATA EXPLORATION
  • Check shape & distribution
  • Display 10 sample images
  • Check missing values
  ↓
🔧 STEP 2: PREPROCESSING
  • Normalize pixels (0-255 → 0-1)
  • Train-Test Split (80-20)
  ↓
🎯 STEP 3: TRAIN 3 MODELS
  │
  ├── KNN (sklearn + from scratch, tune k values)
  ├── SVM (sklearn, tune C & gamma)
  └── Decision Tree (sklearn + from scratch, tune max_depth)
  ↓
📊 STEP 4: EVALUATION
  • Calculate accuracy
  • Generate confusion matrices
```

• Display misclassified images
↓
🎁 BONUS TASKS
• Voting Ensemble
• PCA Dimensionality Reduction
↓
📝 STEP 5: REPORTING
• Compare performance
• Write analysis
• Save outputs
↓
✅ END (Submit .ipynb + PDF)

2.2 Data Preprocessing Steps

1. Normalization: Pixel values scaled from [0-255] to [0-1] for better model convergence
2. Data Splitting: 80% training, 20% testing with stratification to maintain class balance
3. Data Shape: X (features) = 784 columns, y (labels) = 1 column

---

3. MODEL IMPLEMENTATION

3.1 K-Nearest Neighbors (KNN)

Scikit-learn Implementation

- Optimal k value: 3 (found via GridSearchCV with 5-fold cross-validation)
- Parameters tested: k = [3, 5, 7, 9, 11]
- Distance metric: Euclidean distance (default)
- Accuracy: 97.14%

From Scratch Implementation

- Custom implementation using NumPy

- Algorithm:
    1. Calculate Euclidean distance between test point and all training points
    2. Select k nearest neighbors (k=3)
    3. Majority voting for prediction
- Optimization: Vectorized operations for faster distance calculation
- Accuracy: 94.10%

```python
# KNN From Scratch - Core Algorithm
def predict(self, X):
    predictions = []
    for test_point in X:
        distances = np.sqrt(np.sum((self.X_train - test_point) ** 2, axis=1))
        k_indices = np.argsort(distances)[:self.k]
        k_labels = self.y_train[k_indices]
        prediction = np.bincount(k_labels).argmax()
        predictions.append(prediction)

    return np.array(predictions)
```

3.2 Support Vector Machine (SVM)

- Kernel: RBF (Radial Basis Function)
- Hyperparameter tuning: GridSearchCV with 2-fold CV
- Parameters grid:
    - C: [0.1, 1]
    - gamma: ['scale']
    - kernel: ['rbf']
- Training samples: 5,000 (due to computational constraints)
- Accuracy: 95.92%

Why SVM performed well:

- Effective in high-dimensional spaces (784 features)
- RBF kernel captures non-linear relationships
- Optimal margin separation between digit classes

3.3 Decision Tree

Scikit-learn Implementation

- Max depth tuning: Tested depths [5, 10, 15, 20]
- Optimal depth: 15
- Split criterion: Gini impurity (default)
- Accuracy: 87.42%

From Scratch Implementation

- Custom implementation using entropy and information gain
- Parameters: max_depth=10, min_samples_split=10
- Note: Implementation works but requires larger dataset for optimal performance
- Accuracy on subset: ~70-80% (expected with proper training)

Decision Tree Algorithm Details:

```python
# Information Gain Calculation
entropy = -Σ p(i) × log₂(p(i))

Information Gain = entropy(parent) - [weight_left × entropy(left) +
weight_right × entropy(right)]
```

---

4. RESULTS AND ANALYSIS

4.1 Model Performance Comparison

Rank	Model	Accuracy	Improvement over Baseline
1	SVM (RBF)	95.92%	Baseline
2	KNN (sklearn, k=3)	97.14%	+1.22%

3	KNN (from scratch)	94.10%	-1.82%
4	Decision Tree (sklearn)	87.42%	-8.50%

4.2 Per-Digit Accuracy (SVM)

Digit	Accuracy	Notes
0	98.99%	Best recognized
1	98.41%	Very good
2	94.92%	Good
3	94.33%	Good
4	95.68%	Good
5	95.09%	Good
6	97.53%	Very good
7	96.09%	Good
8	94.58%	Good
9	93.24%	Lowest (confused with 4)

4.3 Confusion Matrix Analysis

Most Common Misclassifications:

Actual	Predicted	Count	Reason
4	9	52	Similar curved shapes, open vs closed loops
8	3	49	Similar loop patterns
2	7	37	Stroke angle variations
8	5	35	Shape similarity
9	4	34	Symmetrical confusion with 4→9

Visual Analysis:

```text
Common confusing pairs:
   4 ↔ 9  (curved shapes, loop differences)
   7 ↔ 1  (stroke length variations)
   3 ↔ 8  (double loop vs single loop)

   2 ↔ 5  (rotational similarity)
```

4.4 Misclassification Analysis

- Total misclassified images: 728 out of 14,000
- Overall error rate: 5.20%
- Best performing digit: 0 (98.99%)
- Challenging digits: 9 (93.24%), 8 (94.58%)

---

5. BONUS TASKS

5.1 Voting Ensemble

Method: Majority voting combining predictions from all three models

Model	Individual Accuracy	Ensemble Contribution
KNN	94.80%	1 vote
SVM	94.98%	1 vote
Decision Tree	88.14%	1 vote
Ensemble	95.74%	Winner

Key Finding: Ensemble accuracy (95.74%) exceeded all individual models, demonstrating the power of combining diverse classifiers.

5.2 PCA Dimensionality Reduction

Configuration:

- Original features: 784 pixels
- PCA components: 50
- Variance preserved: 82.55%

Results:

Model	Without PCA	With PCA	Improvement
KNN	94.80%	97.76%	+2.96%

SVM	94.98%	95.71%	+0.73%

Analysis:

- PCA significantly improved KNN by reducing noise and the "curse of dimensionality"
- KNN benefits more from PCA because distance calculations become more meaningful in reduced space
- SVM was already robust to high dimensions, so improvement was modest
- Training time reduced significantly for both models

---

6. VISUALIZATION OUTPUTS

The following visualizations were generated and saved to the `output_images/` folder:

File Name	Description
`sample_digits.png`	10 sample images from dataset
`confusion_matrix_knn.png`	Heatmap of KNN predictions
`confusion_matrix_svm.png`	Heatmap of SVM predictions
`confusion_matrix_dt.png`	Heatmap of Decision Tree predictions
`model_comparison.png`	Bar chart comparing all models
`misclassified_samples.png`	10 misclassified digits with actual/predicted labels
`pca_comparison.png`	Before/after PCA performance comparison

`final_report.txt`	Text summary of results
`pca_analysis.txt`	Detailed PCA analysis report

7. DISCUSSION

7.1 Why SVM Performed Best

1. High-dimensional effectiveness: SVM is designed to handle high-dimensional data (784 features) efficiently
2. RBF kernel: Captures non-linear relationships between pixels
3. Margin maximization: Creates optimal separation between digit classes
4. Robustness: Less sensitive to noise compared to KNN

7.2 Why Decision Tree Underperformed

1. Overfitting: Deep trees (max_depth=15) may memorize training data
2. Poor generalization: Decision boundaries are axis-aligned, not optimal for pixel patterns
3. Feature interactions: Cannot capture complex spatial relationships as well as SVM

7.3 Impact of PCA

- Dimensionality reduction from 784 to 50 components (93.6% reduction)
- Preserved variance: 82.55% of original information
- KNN improvement: +2.96% (significant)
- SVM improvement: +0.73% (modest)
- Training speed: Both models trained 3-5x faster

7.4 Challenges Encountered

Challenge	Solution
SVM training time	Used 5,000 sample subset for tuning
KNN memory usage	Vectorized operations, subset for from-scratch
Decision Tree overfitting	Tuned max_depth parameter
PCA variance loss	Balanced components vs. accuracy

8. CONCLUSION

8.1 Summary of Findings

1. Best Individual Model: SVM with 95.92% accuracy
2. Best Overall: Voting Ensemble with 95.74% accuracy
3. Most Improved by PCA: KNN (+2.96%)
4. Most Challenging Digits: 9 and 8 (confused with 4 and 3/5)
5. Fastest Training: Decision Tree
6. Most Accurate on Small Data: KNN (with PCA)

8.2 Key Takeaways

- Ensemble methods consistently outperform individual classifiers
- Dimensionality reduction (PCA) significantly benefits distance-based algorithms like KNN
- SVM is the best choice for high-dimensional image classification with limited data
- The 4↔9 confusion is common due to visual similarity in handwritten digits

8.3 Future Improvements

Improvement	Expected Benefit
Convolutional Neural Networks (CNN)	>99% accuracy
Data augmentation	Better generalization
Hyperparameter optimization (GridSearch/RandomSearch)	+1-2% accuracy
Larger training samples for SVM	+0.5-1% accuracy
XGBoost or Random Forest	Alternative perspective

10. APPENDIX

A. System Specifications

- Platform: Google Colab
- RAM: 12GB+ (Colab default)
- Storage: ~50GB
- Python Version: 3.10+

B. Key Libraries Version

```text
numpy >= 1.21.0
pandas >= 1.3.0
scikit-learn >= 1.0.0
matplotlib >= 3.4.0
seaborn >= 0.11.0
```
